**APPENDIX M**

End of Construction Season Decontamination

---

**APPENDIX M: BOEING PLANT 2 DSOA  
CORRECTIVE MEASURE AND HABITAT PROJECT,  
DEMOBILIZATION AND DECONTAMINATION**

---

Prepared For:

Boeing

September 2015

## **I. INTRODUCTION**

---

The purpose of this document is to detail the general sequence of work and the typical procedures that were used for decontamination and demobilize of equipment used for the Boeing DSOA project. This document also details the decontamination and restoration procedures used for the south shoreline.

## **II. OVERVIEW**

---

### **REQUIREMENTS**

---

1. The Contractor shall completely remove all mud, sediment, and dirt from all equipment prior to removing equipment from the site at the end of Work. The Contractor shall brush and/or spray wash equipment as needed to remove mud, sediment, and dirt (Construction Specifications Section 01705 3.02).
2. Remove all equipment, material, and temporary facilities from the site, unless otherwise requested or approved by the Owner.
3. Restore pavement and planting to the original condition, unless otherwise approved by the Owner.

### **SUMMARY**

---

After completion of sediment generating remedial tasks for the Boeing DSOA Project Area, decontamination and demobilization activities commenced. The decon process started with barges and other on-water equipment. After on-water equipment decon was completed the demobilization of each separate area of the Dredge Return Water System (DRWS) began. Table 1 detail the decontamination method used for South Shoreline equipment and Table 2 of this document documents the completion date, sample date, and whether the sample met criteria for each area/piece of equipment. The sediment processing area (SPA) was deconned first, followed by the polishing step and then the settling basin. As decon and demob activities were completed, site restoration began. The site was restored to an equipment and debris free work area and the site was left clean and generally in the same condition as it was prior to starting the work, or as otherwise noted in other project documents.

Water generated from decontamination activities that did not contain decontamination chemicals or surfactants were managed in the DRWS or in one of the options listed below.

1. Decon water was collected and transported to Lafarge for treatment through their wastewater treatment system and subsequent discharge to King County under Lafarge's permit. Lafarge's wastewater treatment system had the ability to receive up to 25,000 gallons of wastewater a day.
2. Decon water was collected and transported to be treated at the North Boeing Field Treatment System. The North Boeing Field Treatment System had the ability to receive and process up to 15,000 gallons of wastewater a day depending on how much wastewater was being processed from other activities and processes.

## **III. DECONTAMINATION PROCEDURE**

---

For bulk sampling the decision criteria was 1 ppm, which is consistent with PCB residential action levels. The decision criteria for wipe samples was non-detect (ND) and met vendor's standards. All sampling followed EPA method 8082 and was conducted according to a written sampling and analysis plan, including Quality Assurance Project Plan. See Table 1 for specific decision criteria for each item.

---

## **A. ON WATER EQUIPMENT**

---

The on-water equipment included metal pilings, outfall piping, and barges. The decontamination methods implemented are detailed below.

### **1. Metal Piling**

Metal piling was pressure washed to remove any visible sediment. Water from decon of piling pumped to DRWS settling basin.

### **2. HDPE Piping**

No decon required for outfall piping. Outfall piping includes temporary outfall Z and DRWS outfalls. Floating pipe used for dewatering sediment barges was thoroughly flushed and cut into 50 foot lengths and placed into 400 foot linear feet groups. The pipe was then visually inspected and 1 wipe sample per group was collected. All wipe samples collected were non-detect.

### **3. Mobile Equipment**

Mobile equipment includes the Aberdeen barge, DB Skookum, the sediment barges, and the PC 800 excavator. All equipment and structures that have been in contact with liquid or non-liquid PCB remediation waste was decontaminated using mechanical means or pressure washing to achieve a "clean debris surface", as described in the CS3 RBDA. The sediment barge decon procedures are documented in the Boeing Duwamish Sediment Other Area Corrective Measure and Habitat Project: Sediment Barge Decontamination Procedures report.

---

## **B. SEDIMENT PROCESSING AREA (SPA)**

---

The SPA includes the Tri-Flo, ecology blocks, asphalt, gravel, and liners. Decon methods for each item is detailed below.

### **1. Tri-Flo**

Philip Service Corp. (PSC) conducted decon of the Tri-Flo using a surfactant and a double wash and rinse process. Decon procedure for the Tri-Flo consisted of first pressure washing the equipment, then spraying surface with surfactant and agitating the surfactant with a brush, letting it sit for 10-15 minutes, then pressure washing again, and then repeating the procedure a second time. Five wipe samples at random locations were collected after decon of the Tri-Flo was completed. All samples were non-detect.

### **2. Ecology Blocks**

The ecology blocks were handled differently based on if the block was in contact with dredged material or if the block was covered by a liner. Blocks covered by a liner were visually inspected to verify that the block did not come in contact impacted sediments. Blocks not covered by a liner were pressure washed and placed into groups of 30 blocks. QA/QC involved random sampling of 1 block from the group of

30. Sampling protocol required the use of a rotary hammer that was used extract enough volume of material from around the block. Samples were taken near the bottom of the block on the side that was previously in contact with impacted sediment. All samples were non-detect. Broken ecology blocks were recycled.

### 3. Asphalt

Asphalt was pressure washed followed by sampling while the asphalt was still in place. Sampling protocol involved breaking the asphalt up by a hammer and chisel in order to collect sufficient sample volume. Sample locations are shown in Figure 1 and frequency was based on different levels of potential previous contact with contaminated materials for each area. All samples were non-detect. All asphalt was recycled.

### 4. Gravel

Gravel was stockpiled in approximate 100 CY piles with one composite sample per pile. All samples were non-detect. ~500 CY of gravel was left onsite for future use. Remaining material was used to build up the shoreline access/maintenance road or exported to other Boeing facilities.

### 5. Liners

Liners were disposed of at an appropriate Subtitle D facility.

### 6. Mobile Equipment

All mobile equipment, including trucks, loaders, and excavators were pressure washed with the water being contained and either processed onsite or trucked to Lafarge or North Boeing field for processing.

---

## C. SETTLING BASIN

---

The settling basin consisted of ecology blocks, asphalt, gravel, liners and mobile equipment. All of these were deconned as previously described in section III.B. (2-6).

---

## D. DREDGE RETURN WATER SYSTEM (DRWS)

---

The polishing step for the DRWS consisted of ecology blocks, gravel, liners, clarifier, cone tanks, sand filters, bag filters, granular activated carbon (GAC) vessels, electrocoagulation (EC) units, pumps and miscellaneous tanks. The decontamination methods for each item are detailed below.

1. Ecology blocks, gravel, and liners were handled as previously described in section III. B. (2, 4, 5).

### 2. Clarifier, Cone Tanks, Filters and Other Tanks

Decon of the clarifier, cone tanks, sand filters, bag filters, GAC vessels, and miscellaneous tanks was performed by PSC and followed methods described in section III.B.1. Wipe samples were collected for each item (sample frequency based on size of item, see Table 1). All wipe sample analytical results were non-detect.

### 3. Sand Filter Media

A single composite sample of the sand filter media was collected to determine proper disposal. The sample analytical results were non-detect. The used media was disposed of at a Subtitle D facility.

#### 4. Granulated Activated Carbon (GAC)

Used GAC was sampled to determine proper disposal. Sample analytical results for Aroclor 1248 detected less than 1 ppm (0.82 mg/kg). All other Aroclors were non-detect. The used media was disposed of at a Subtitle D facility.

#### 5. EC Units

Decon of the EC units was performed by the owner of the units, Baker Corp. (Baker), using the same double wash/rinse with use of surfactant process as done by PSC. One wipe sample per EC unit was collected as QA/QC. All wipe sample analytical results were non-detect. EC units were returned to Baker.

#### 6. Pumps

The pumps were pressure washed on the outside and a double wash/rinse with surfactant were performed for inner portion.

---

### **E. LAYDOWN AREA**

---

The settling basin consisted of ecology blocks, asphalt, gravel, liners and mobile equipment. All of these were deconned as previously described in section III.B. (2, 4, 5).

---

### **F. GENERAL SITE**

---

General site items include ecology blocks, asphalt, pumps, HDPE piping, and catch basins. The decontamination procedures and methods for these items are detailed below.

#### 1. Ecology Blocks

The blocks in this area followed the procedures as described in section III.B.2.

#### 2. Asphalt

The asphalt in the general site area included asphalt berms installed as pipe crossings as well as the base layer original asphalt. The asphalt berms were pressure washed prior to removal and recycled at an appropriate facility per section III.B.3. After the removal of all asphalt overlays, gravel and liners the base asphalt was inspected to identify areas in need of repair. In some areas the base asphalt layer was removed and repaved with new asphalt. Minor damage areas were patched. After all asphalt repairs were complete the asphalt was cleaned in quadrants as shown in Figure 2. To clean each quadrant a water truck saturated the asphalt and a power sweeper brushed the asphalt. The water truck and a pressure washer were then used clean the quadrant by pushing water towards the catch basin located in the center of the quadrant. A vac-truck vacuumed up the water as it entered the catch basin sump. The water produced from this process was taken to the North Boeing Field treatment plant for processing.

#### 3. Pumps

A fresh water flush performed to decon pumps used for rain water and low PCB concentration areas. A double wash and rinse recirculation with surfactant as described in section III.B.3 was performed to decon pumps in higher PCB concentration areas.

#### 4. HDPE Piping

The HDPE piping was deconned by performing a freshwater flush. The piping was then cut into 50 lengths and placed into 400 foot linear feet groups. The pipe was

then visually inspected and 1 wipe sample per group was collected. All wipe samples collected were non-detect.

#### 5. Catch Basins

Each catch basin was jetted after the decontamination of each area was completed. The water produced from this process was taken to the North Boeing Field treatment plant for processing as shown in Figure 3.

---

### **G. TRANSLOAD FACILITY**

---

All equipment and structures at Lafarge that have been used for Boeing DSOA project were deconned according to Waste Management's Work Plan. Photos documenting typical decontamination of railcars used on the project have been included in section VII of this report.

---

## **IV. CONCLUSION**

---

All equipment and material were deconned and demobed at the end of CS3 without incident.

## **TABLES**

---

---

This Page Intentionally Left Blank

Table 1: South Shoreline Equipment Decon Methods, QA/QC, and Criteria

Area	Item	Use (over/Under 50 PPM Material)	Decon Method	QA/QC	Decision Criteria
ON-WATER EQUIP.	Metal piling	<50 ppm	Pressure wash	Visual Inspection	N/A
	Outfall piping	<50 ppm	Fresh water flush	none	N/A
	Equipment	none	Pressure wash	Visual Inspection	N/A
SPA	Triflow	tsca	Stericycle decon *	5 wipe samples	If sample > ND, repeat decon process and verification sampling until ND result is obtained.
	Ecology blocks	covered by liner	none	Visual Inspection	N/A
	Ecology blocks	tsca	Pressure wash	Blocks placed in approx. 15-30 block groups and sampled by 1" diameter rotary hammer bit to 1" depth; samples taken until sufficient sample volume achieved. Collect from bottom half of block on the side in contact. 1 sample/ approx. 15-30 blocks.	If sample < 1 ppm reuse/resale/recycle. If sample > 1 ppm the 15-30 associated blocks disposed Subtitle D. If sample > 50 ppm the 15-30 associated blocks disposed Subtitle C.
	Asphalt	<50 ppm	Pressure wash	9 samples collected while asphalt is in place. Sample locations Figure 1.	If sample < 1 ppm recycle. If sample > 1 ppm associated volume disposed subtitle D. If sample > 50 ppm associated volume disposed Subtitle C.

CORRECTIVE MEASURE AND HABITAT PROJECT:  
SEDIMENT BARGE DECONTAMINATION  
PROCEDURES**

---

Prepared For:

Boeing

**DOF** DALTON  
OLMSTED  
FUGLEVAND

March 2015

## **I. INTRODUCTION**

---

The purpose of this document is to detail the sequence of events and methods and procedures used to decontaminate the sediment barges utilized during the 2014-2015 Construction Season 3 (CS3) as part of demobilization activities for the Boeing Duwamish Sediment Other Area (DSOA) Corrective Measure and Habitat Project.

## **II. OVERVIEW**

---

### **A. REQUIREMENTS**

---

1. The Contractor shall completely remove all mud, sediment, and dirt from all equipment prior to removing equipment from the site between in-water CS and at the end of Work. The Contractor shall brush and/or spray wash equipment as needed to remove mud, sediment, and dirt (Construction Specifications Section 01750 3.02).
2. Equipment and barges visually inspected and photographed to document completion of decontaminated prior to departing the DSOA.

### **B. SUMMARY**

---

At the completion of CS3 and final offload, residual sediment and water remained in each barge. This material remained in the barges after final offload due to limitations of the gantry crane's ten cubic yard bucket used for offload at the TTD. Remaining water and solids were required to be removed from each of the barges prior to departing the DSOA as part of the decontamination procedure at the end of each construction season. The photo below of the 101 Barge after offload is a typical example of material and water remaining each barge after final offload.

Offloaded 101 Barge: Example of Remaining Material in Barges after Offload

## **III. DECONTAMINATION PROCEDURE**

---

Decontamination of the sediment barges required the use of the following equipment: skid steer loader, pressure washers, pumps, and hand tools. The skid steer was loaded on to each barge for

bulk removal of solids by consolidating remaining solids; stacking the material in a corner within the dredge’s PC800 excavator swing radius. The PC800 was then used to transfer this material to one sediment barge (barge 104). Remaining material on each sediment barge after bulk solids removal was slurried and pumped to the Dredge Water Return System (DWRS) settling basin. Barge bin walls and decks were cleaned of all residual sediment. After the 100, 101, and 166 barges were decontaminated the 104, with consolidated solids from these barges, was taken to the TTD for offload. To assist with this final offload, the skid steer was loaded into the 104. The skid steer consolidated material for the gantry crane. Sediment from the 104 barge was disposed of with remaining dredged sediment from CS3 dredging. The 104 was then taken back to the DSOA. Any remaining material was slurried and pumped to the DWRS retention pond.

The 135 barge was initially gross deconned. The bulk of the material was transferred to the 104 barge before the 104 barge was sent to the TTD for final offload using the same methods as the other sediment barges. Once the 135 barge was sufficiently decontaminated it was put back into service and used for pile removal and decontamination. Final decontamination of the 135 barge occurred after pile removal and pile decontamination was complete. To perform final decontamination of the 135 barge a vac-truck was brought to the slip 4 dock where the remaining sediment in barge was slurried and removed by the vac-truck. This slurry was then transported to the DRWS and placed within the settling pond where it was removed during DRWS decontamination. Photos of each barge after decontamination attached.

Barge Number	Decon Start	Decon Complete	Demobe
100	2/23/2015	2/25/2015	2/28/2015
101	2/25/2015	2/26/2015	2/28/2015
104	2/26/2015	2/28/2015	3/3/2015
135	2/24/2015	3/12/2015	3/12/2015
166	1/8/2015	1/15/2015	2/28/2015

Table 1: Sediment Barge Decontamination & Demobilization Schedule

## IV. CONCLUSION

The standard for successful decontamination of a sediment barge was that there was no visible sediment remaining on a barge. Once the contractor determined that decontamination of a barge was complete, the designated Boeing representative was notified and the barge was visually inspected for the presence of sediment. Noted deficiencies were recorded and the contractor required to correct these deficiencies prior to re-inspection. Only when a barge passed visual inspection, was it released from the site. All of the sediment barges were deconned at the end of CS3 without incident. Lessons learned from CS1 & CS2 and implemented for CS3 increased the efficiency and ease of decon resulting less time spent decontaminating equipment at the end of the final construction season.
